

Optical splitter splits light into two causing optical attenuation

Overview

In the context of beam splitters, attenuation can occur due to several factors, including absorption, reflection, and scattering. In a Passive Optical Network (PON), a single optical fiber carries massive amounts of data using light. Instead of running separate cables for each user or device, a central piece of equipment—called an Optical Line Terminal (OLT) —sends data down the line to multiple Optical Network Terminals. Optical splitters play a crucial role in Fiber to the Home (FTTH) Passive Optical Network (PON) systems, efficiently distributing a single optical signal to multiple destinations. Conversely, it can also combine multiple signals into one. Depending on the design, beam splitters can either reflect a portion of the incoming light and transmit the rest. Beamsplitters are optical components used to split incident light at a designated ratio into two separate beams. It is one of the most important elements of all FTTx PON and OLAN networks.
