

Principle of Fiber Optic Fusion Splicer

Overview

Optical fusion splicer joins two optical fibers by melting end faces using an electric arc, creating a permanent bond with minimal signal loss. As explained in industry resources, this technique achieves insertion losses as low as 0. Fusion splicing is the most widely used method of splicing as it provides for the lowest loss and least reflectance, as well as providing the strongest and most reliable joint between two fibers. The goal is to fuse the two fibers together in such a way that light passing through the fibers is not scattered or reflected back by the splice, and so that the splice and the region surrounding it are almost as strong as the. It is a technique that uses controlled heat to permanently fuse two optical fiber ends together. The result is a joint that closely matches the. Before optical fibers can be successfully fusion-spliced, they need to be carefully stripped of their outer jackets and polymer coating, thoroughly cleaned, and then precisely cleaved to form smooth, perpendicular end faces. Once all of this has been completed, each fiber is placed into a holder in.
