

Understanding Fiber Bragg Gratings in One Picture

Overview

A fiber Bragg grating (FBG) is a type of distributed Bragg reflector constructed in a short segment of optical fiber that reflects particular wavelengths of light and transmits all others. This is achieved by creating a periodic variation in the refractive index of the fiber core, which generates a wavelength-specific dielectric mirror. Hence a fiber Bragg grating can be used as an inline optical filter to block. HistoryThe first in-fiber Bragg grating was demonstrated by in 1978. Initially, the gratings were fabricated using a visible laser propagating along the fiber core. In 1989, Gerald Meltz and colleagues demonstrated. The fundamental principle behind the operation of an FBG is, where light traveling between media of different refractive indices may both and at the interface. The refractive. The term type in this context refers to the underlying mechanism by which grating fringes are produced in the fiber. The different methods of creating these fringes have a significant effect on physical att.
