

What is the red light source in a fiber optic transceiver

Overview

A visual fault identifier or visual fault locator (VFI / VFL) is a visible red laser designed to inject visible light energy into a fiber. Sharp bends, breaks, faulty connectors and other faults will “leak” red light allowing technicians to visually spot the defects. The red light of a laser is coupled into the core of an optical fiber in a targeted manner (an LED is usually too weak a source to be used instead). The light from the end of the fiber is coupled to a receiver where a detector converts the light into an electrical signal which is then conditioned properly for use by. A fiber optic transceiver (also called an optical transceiver) is a compact module that both transmits and receives data signals through optical fibers. In practical systems, these light sources are almost always semiconductor diode lasers or LEDs. The VFI is an ideal tool for.
