

What type of cable tray should be used for wiring in the distribution box

Overview

Wire mesh cable trays—often called basket trays—are constructed from welded steel wire, forming a lightweight open-grid structure. Unlike traditional formed trays, wire mesh trays rely on distributed wire intersections for strength rather than solid rails or rungs. Cable tray systems are engineered support structures designed to route, support, and protect insulated electrical cables used for power distribution, control, instrumentation, and communication. Unlike conduit systems, cable trays allow cables to be laid in bundles, improving accessibility, heat maintenance, spacing, or to keep cables in place when the tray is subjected to the minimum bend radius for cables as they exit the bottom of the cable tray. A rung spacing of 6 to 9 inches (150 to 230 mm) is preferable when the cable tray is intended for instrumentation and control applications that require. There are several types of cable trays, including ladder, perforated, solid bottom, basket, and channel trays. Think of it as a sophisticated “highway” for cables, keeping them organized, protected, and easily accessible. What is the difference between ladder tray and
