

Why can't cold-joints be used

Overview

A cold joint in concrete construction is a plane of weakness that forms when new, wet concrete is poured against concrete that has already begun to harden. This discontinuity occurs because the older material has passed its initial setting time, preventing a true chemical bond with. To avoid cold joints, several standards provide guidance: These standards highlight the importance of timing, bonding, and workmanship. Here are practical steps used on site: 1. Albeit the most famous one is probably honeycomb, normally associated with inadequate concrete vibration during the pouring process, cold joints are also very frequent on construction sites. The visible change between the two concrete surfaces could be a slight difference in color or texture. A cold joint is a joint that is formed between two pours of concrete when the second concrete pour is placed after starting the setting of the first pour.
